What it Does:
Document method: returns a static (not live) NodeList representing a list of the document's elements that match the specified group of selectors.
Document method getElementById() returns an Element object representing the element whose id property matches the specified string. Since element IDs are required to be unique if specified, they're a useful way to get access to a specific element quickly.
If you need to get access to an element which doesn't have an ID, you can use querySelector() to find the element using any selector.

In an HTML document, the `document.createElement()` method creates the HTML element specified by `tagName`, or an `HTMLUnknownElement` if `tagName` isn't recognized.

Sets the value of an attribute on the specified element. If the attribute already exists, the value is updated; otherwise a new attribute is added with the specified name and value.

To get the current value of an attribute, use `getAttribute()`; to remove an attribute, call `removeAttribute()`.

Creates a new Text node. This method can be used to escape HTML characters.

The `Node.appendChild()` method adds a node to the end of the list of children of a specified parent node. If the given child is a reference to an existing node in the document, `appendChild()` moves it from its current position to the new position (there is no requirement to remove the node from its parent node before appending it to some other node).

This means that a node can't be in two points of the document simultaneously. So if the node already has a parent, the node is first removed, then appended at the new position. The `Node.cloneNode()` method can be used to make a copy of the node before appending it under the new parent. Note that the copies made with `cloneNode` will not be automatically kept in sync.

If the given child is a `DocumentFragment`, the entire contents of the `DocumentFragment` are moved into the child list of the specified parent node.

The `onload` property of the `GlobalEventHandlers` mixin is an `EventHandler` that processes load events on a `Window`, `XMLHttpRequest`, `<img>` element, etc.

The load event fires when a given resource has loaded.

## Syntax:

```
elementList = parentNode.querySelectorAll(selectors);
```

```
const element = document.getElementById(id);
```

```
let element = document.createElement(tagName[, options]);
```

```
Element.setAttribute(name, value);
```

```
var text = document.createTextNode(data);  
text is a Text node.
```

**element.appendChild(aChild)**

### Parameters:

**selectors**

A DOMString containing one or more selectors to match against. This string must be a valid CSS selector string; if it's not, a `SyntaxError` exception is thrown

**id**

The ID of the element to locate. The ID is case-sensitive string which is unique within the document; only one element may have any given ID.

tagName

A string that specifies the type of element to be created. The nodeName of the created element is initialized with the value of tagName. Don't use qualified names (like "html:a") with this method. When called on an HTML document, createElement() converts tagName to lower case before creating the element. In Firefox, Opera, and Chrome, createElement(null) works like createElement("null").

options

Optional

An optional ElementCreationOptions object, containing a single property named is, whose value is the tag name of a custom element previously defined via customElements.define(). See Web component example for more details.

**name**

A DOMString specifying the name of the attribute whose value is to be set. The attribute name is automatically converted to all lower-case when `setAttribute()` is called on an HTML element in an HTML document.

**value**

A DOMString containing the value to assign to the attribute. Any non-string value specified is converted automatically into a string.

**data**

is a string containing the data to be put in the text node.

### **aChild**

The node to append to the given parent node  
(commonly an element).

## Value

functionRef is the handler function to be called when the window's load event fires.

[illegible]

[illegible]

[illegible]

[illegible]

[illegible]

This image shows a full page of blank handwriting practice paper. It features a series of evenly spaced horizontal lines across the entire width of the page. On the left side, there is a vertical dashed line that runs from the top to the bottom, creating a narrow margin. The rest of the page is open space between the horizontal lines, intended for writing practice.

### Returns

A non-live NodeList containing one Element object for each element that matches at least one of the specified selectors or an empty NodeList in case of no matches.

An Element object describing the DOM element object matching the specified ID, or null if no matching element was found in the document.

The new Element.

undefined.

None

The returned value is the appended child (aChild), except when aChild is a DocumentFragment, in which case the empty DocumentFragment is returned.

[illegible]

[illegible]

[illegible]

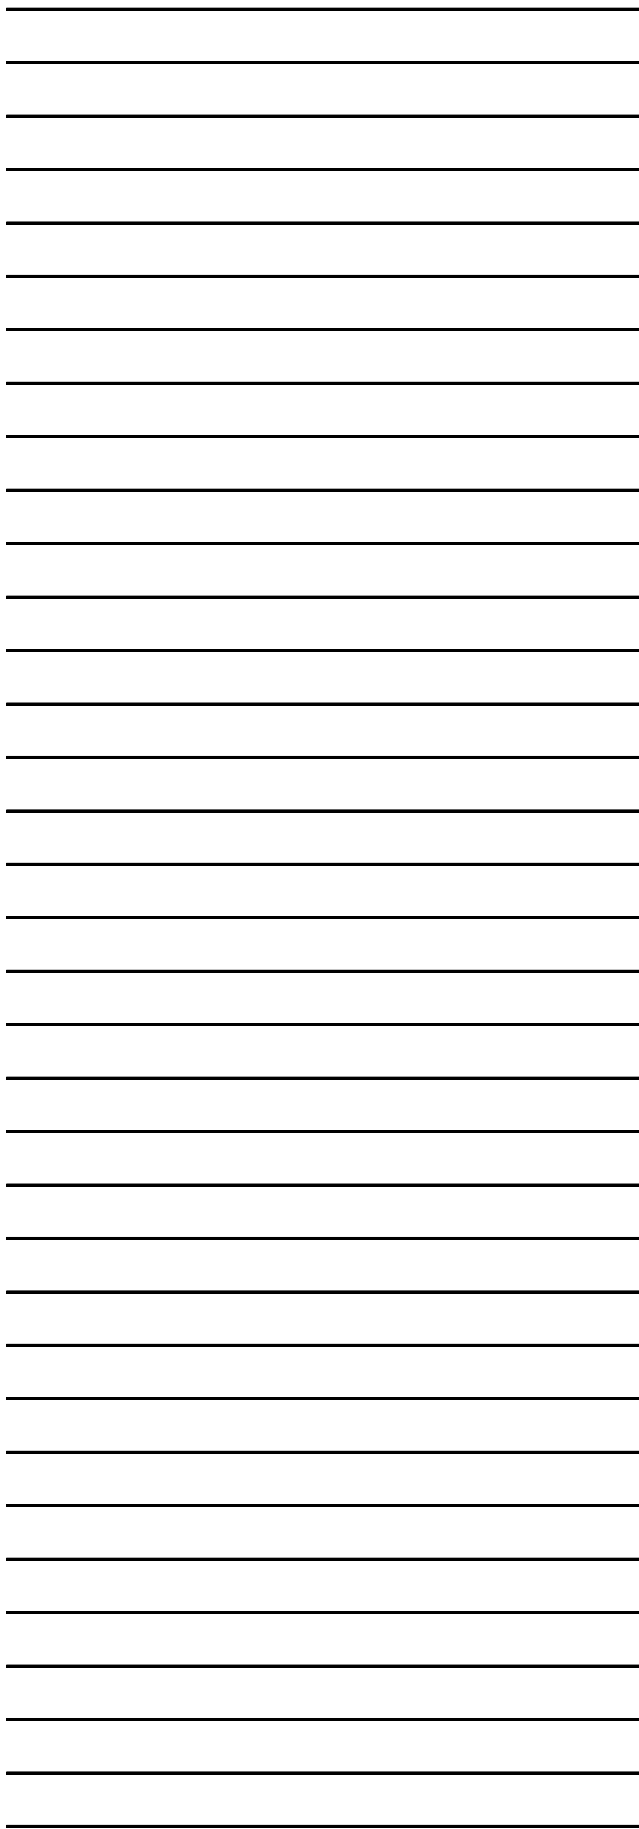

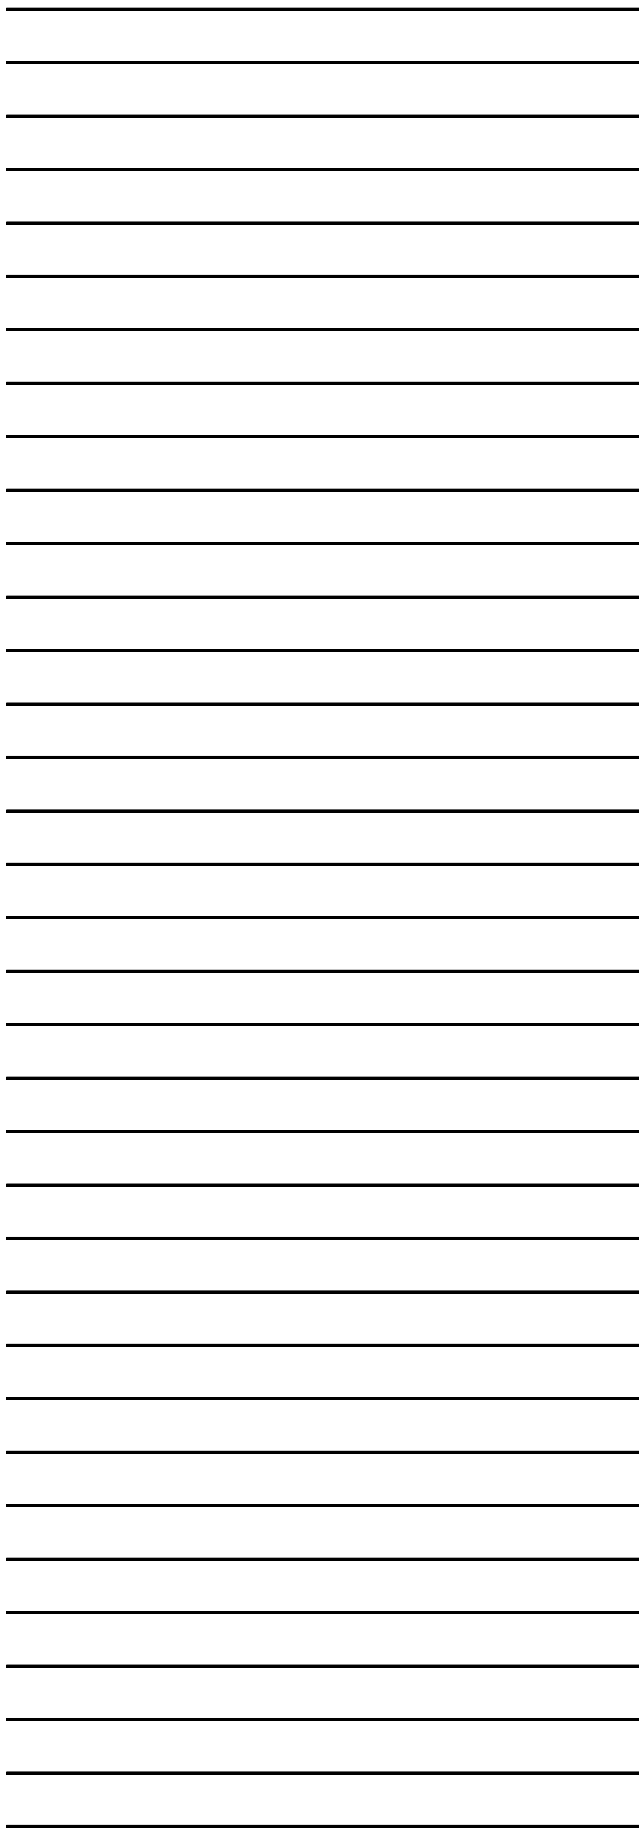

[illegible]

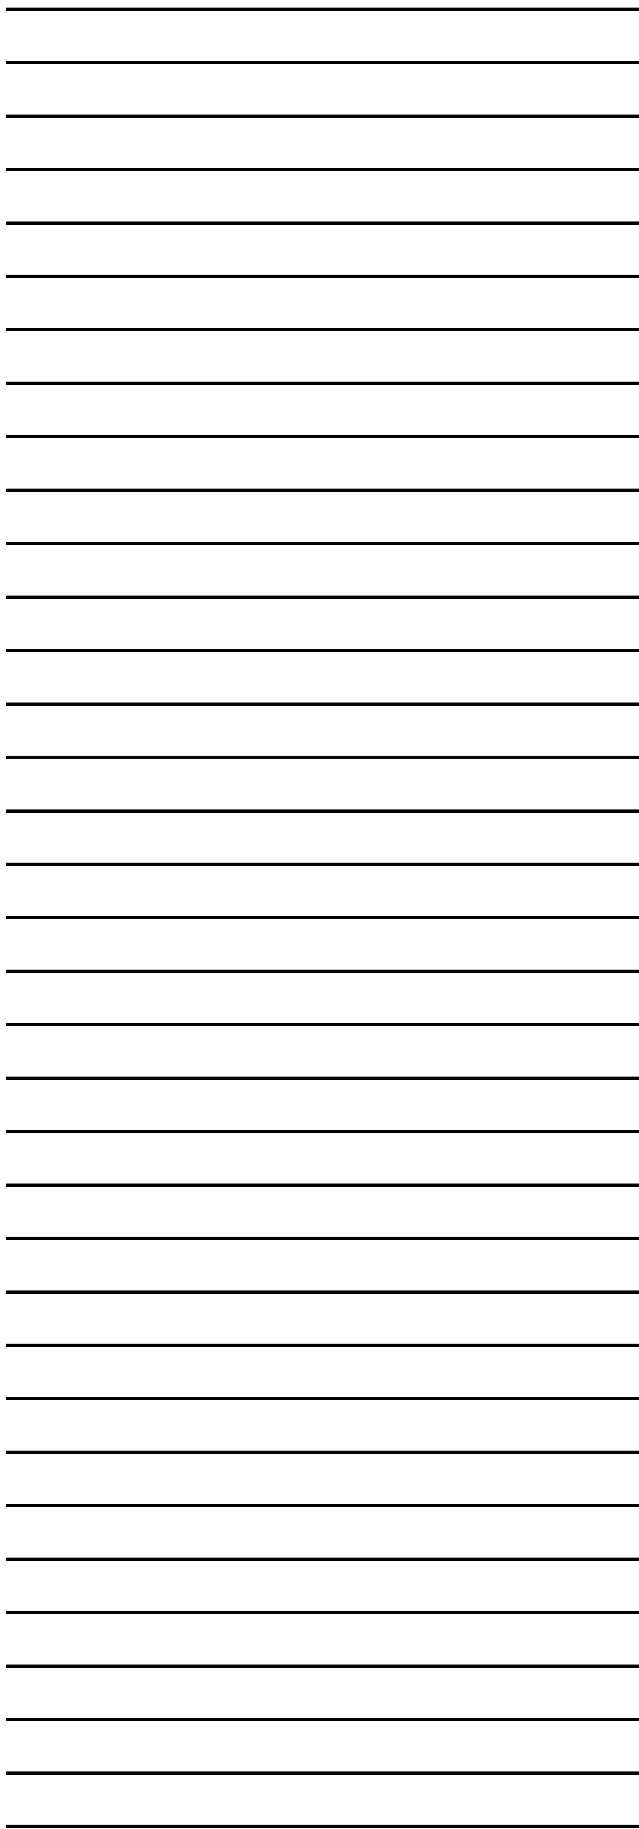

[illegible]

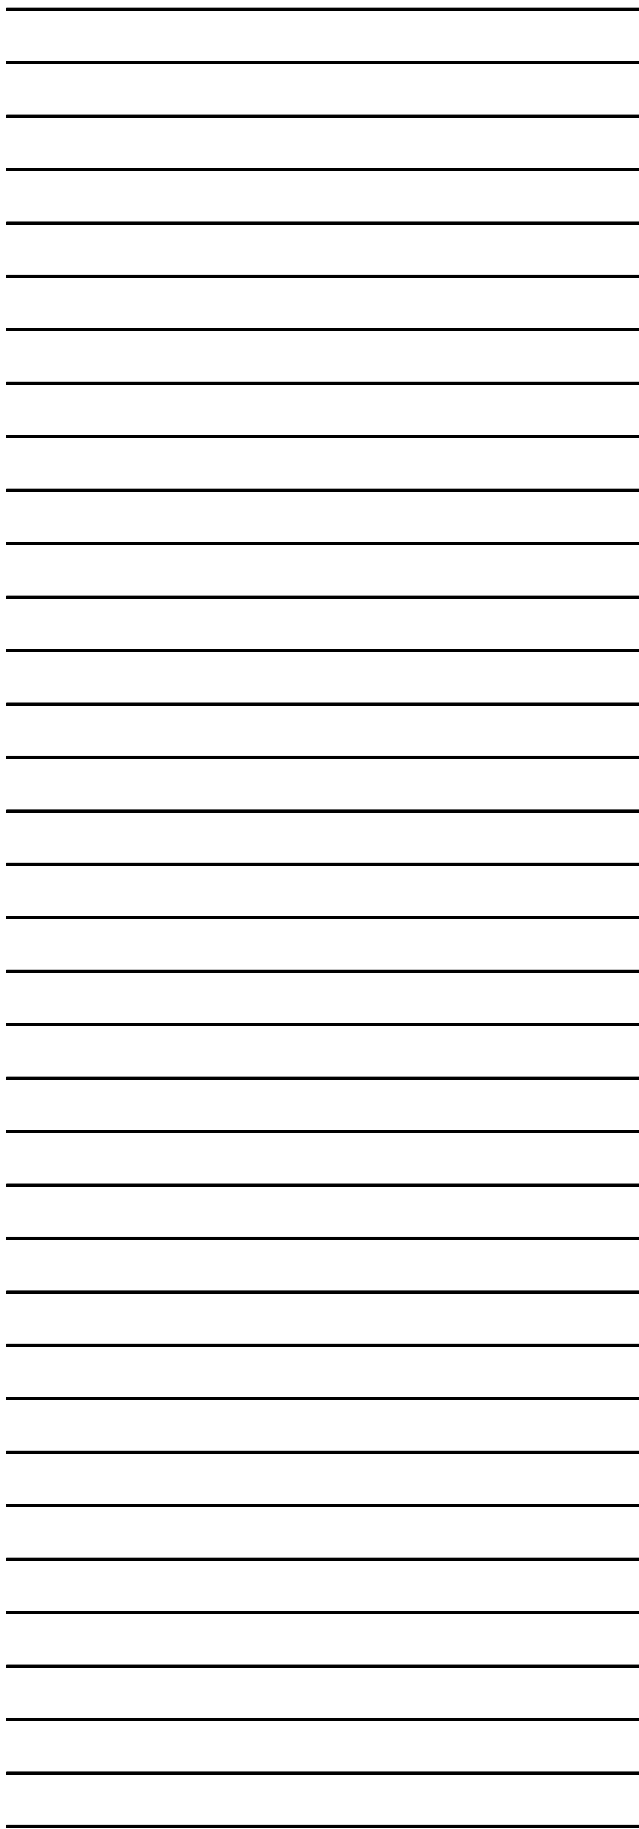

[illegible]

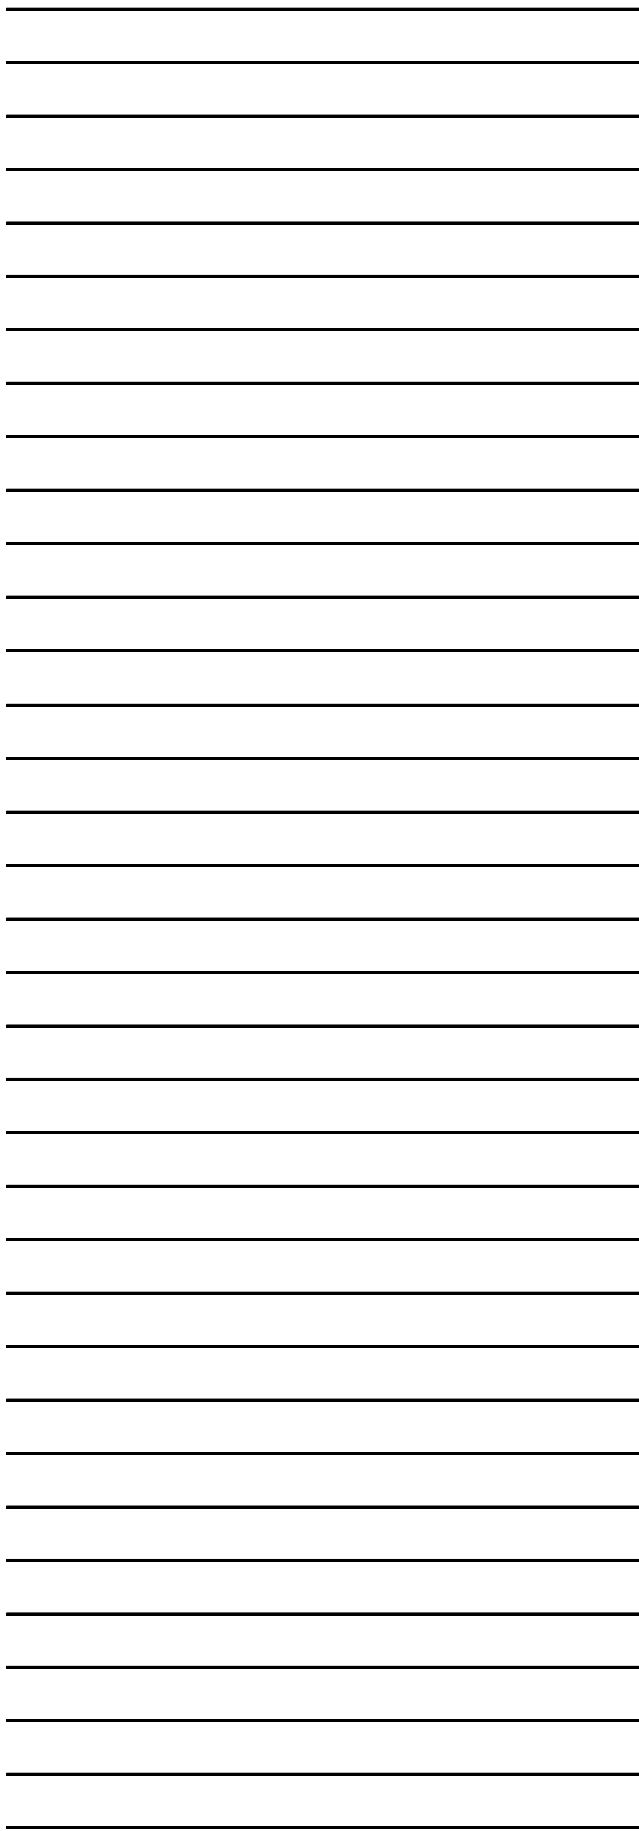

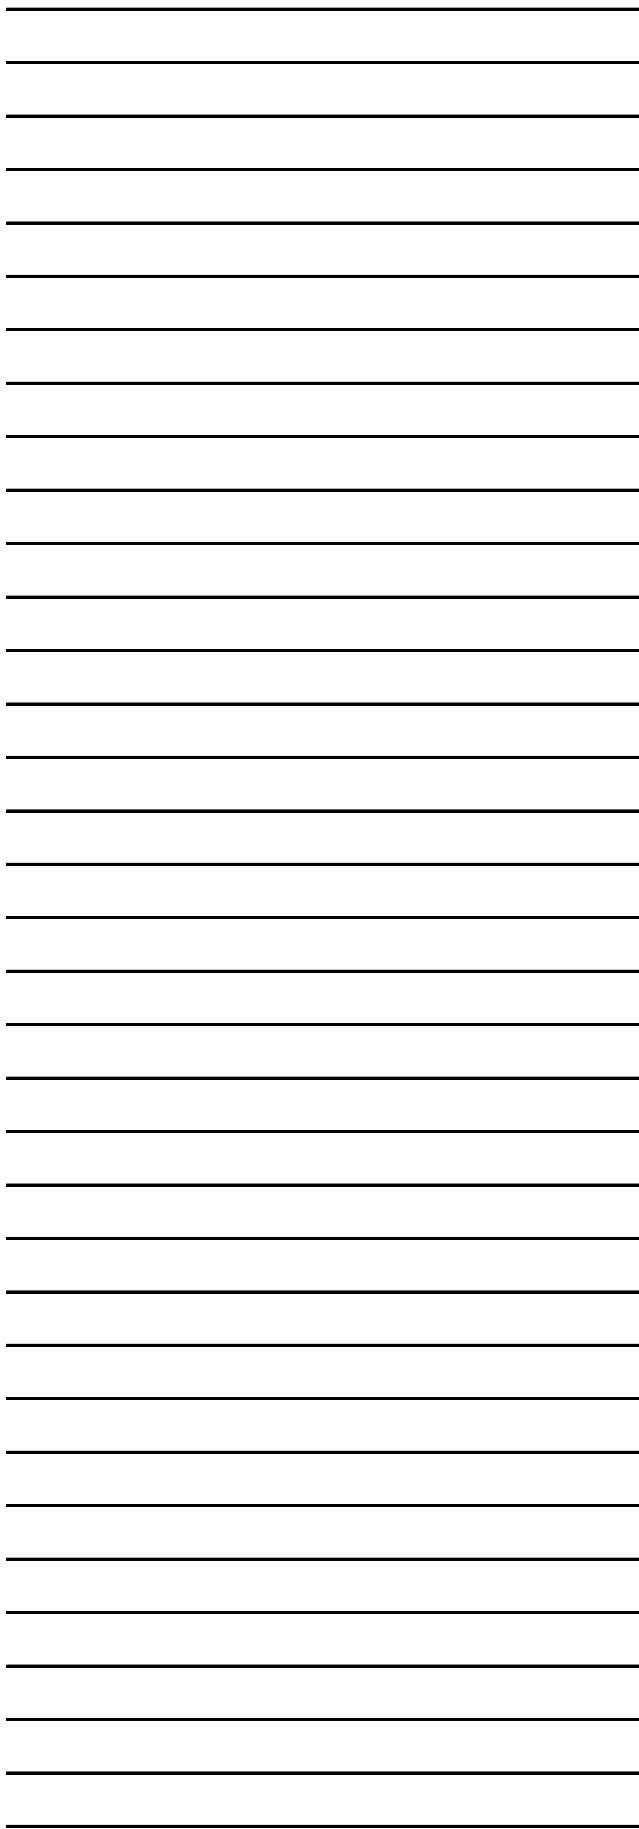

[illegible]

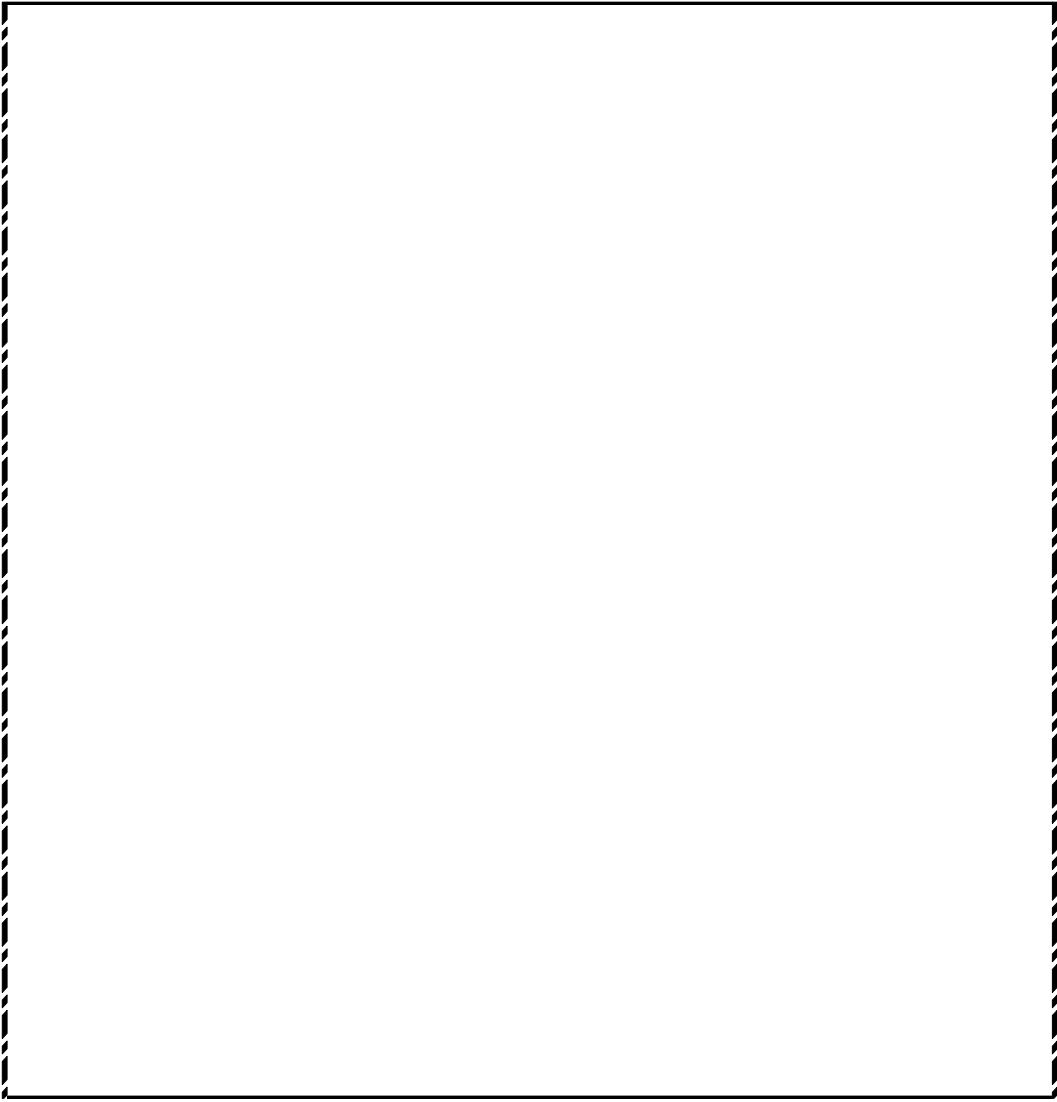

[illegible]

[illegible]

[illegible]

**Note:**

Note: If the specified selectors include a CSS pseudo-element, the returned list is always empty.

**In the example to the right:**

The first call to `setAttribute()` above shows changing the name attribute's value to "helloButton". You can see this using your browser's page inspector (Chrome, Edge, Firefox, Safari).

To set the value of a Boolean attribute, such as `disabled`, you can specify any value. An empty string or the name of the attribute are recommended values. All that matters is that if the attribute is present at all, regardless of its actual value, its value is considered to be true. The absence of the attribute means its value is false. By setting the value of the `disabled` attribute to the empty string (""), we are setting `disabled` to true, which results in the button being disabled.

The `ParentNode.append()` method supports multiple arguments and appending strings.

## Notes

The load event fires at the end of the document loading process. At this point, all of the objects in the document are in the DOM, and all the images, scripts, links and sub-frames have finished loading.

There are also DOM Events like `DOMContentLoaded` and `DOMFrameContentLoaded` (which can be handled using `EventTarget.addEventListener()`) which are fired after the DOM for the page has been constructed, but do not wait for other resources to finish loading.

[illegible]

This image shows a full page of blank handwriting practice paper. It features a series of evenly spaced horizontal blue lines across the entire width of the page. On the left side, there is a vertical dashed line that serves as a margin guide. The paper is otherwise completely blank, with no text or other markings.

---

### Example:

```
const cloudySpans = document.querySelectorAll("span.cloudy");
```

While `getElementById` allows us to reference a single element, `querySelectorAll` references all elements with the class name “cloudy” as a static `NodeList` (*static* meaning that any changes in the DOM do not affect the content of the collection).

---

### Javascript

```
const divOfInterest = document.getElementById("catch-me-if-you-can")
```

Now let’s say that our HTML file contains seven `span` elements that share a class name of `cloudy`, like below:

### HTML

```
<span class=""cloudy""></span>
<span class=""cloudy""></span>
<span class=""cloudy""></span>
<span class=""cloudy""></span>
<span class=""cloudy""></span>
<span class=""cloudy""></span>
<span class=""cloudy""></span>
```

In Javascript, we can reference all seven of these elements and store them in a single variable.

---

# HTML

```
1 <!DOCTYPE html>
2 <html>
3 <head>
4   <title>|Working with elements|</title>
5 </head>
6 <body>
7   <div id="div1">The text above has been created dynamically.</div>
8 </body>
9 </html>
```

```
1 document.body.innerHTML = document;
2
3 function addContent() {
4   // create a new div element
5   const newNode = document.createElement("div");
6
7   // add some text content
8   const result = document.createTextNode("There are 4 paragraphs");
9
10  // add the text node to the newly created div
11  newNode.appendChild(result);
12
13  // add the newly created element and its content into the DOM
14  const currentDir = document.getElementsByTagName("div");
15  document.body.appendChild(newNode, currentDir);
16 }
```

Follow up project  
Create a new file named project.js

---

In the following example, `setAttribute()` is used to set attributes on a `<button>`.

## HTML

```
1 | <button>Hello World</button>
```

## JavaScript

```
1 | var b = document.querySelector("button");  
2 |  
3 | b.setAttribute("name", "helloButton");  
4 | b.setAttribute("disabled", "");
```

---

---

In our `example.js` file, we'll write a function to create a new `h1` element, assign it an `id`, give it content, and attach it to the body of our HTML document.

## Javascript

```
const addElement = () => {
  // create a new div element
  const newElement = document.createElement("h1");

  // set the h1's id
  newElement.setAttribute("id", "sleeping-giant");

  // and give it some content
  const newContent = document.createTextNode("Jell-O, Burled!");

  // add the text node to the newly created div
  newElement.appendChild(newContent);

  // add the newly created element and its content into the DOM
  document.body.appendChild(newElement);
};

// run script when page is loaded
window.onload = addElement;
```

---

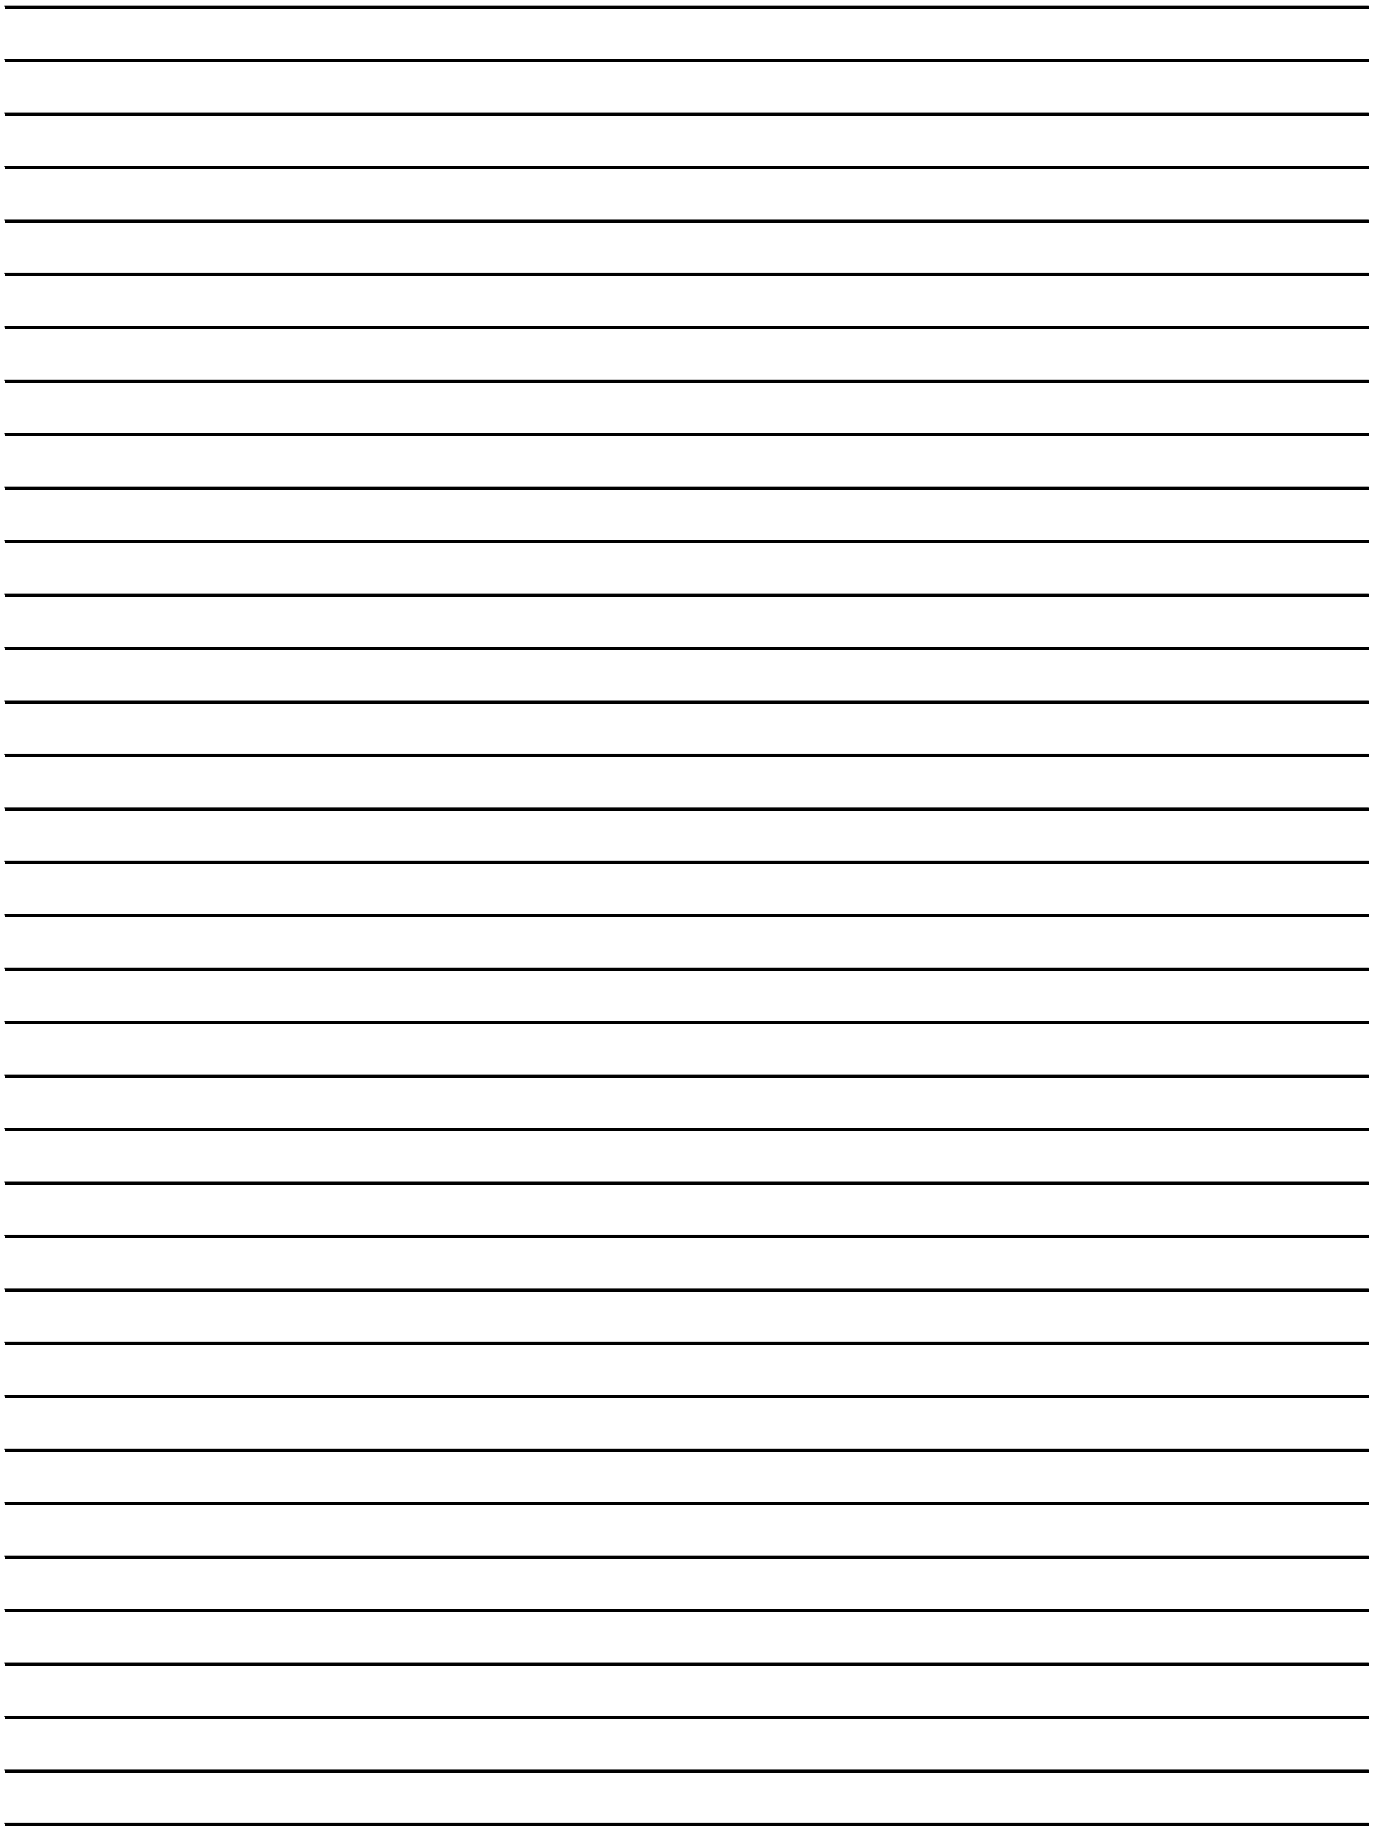

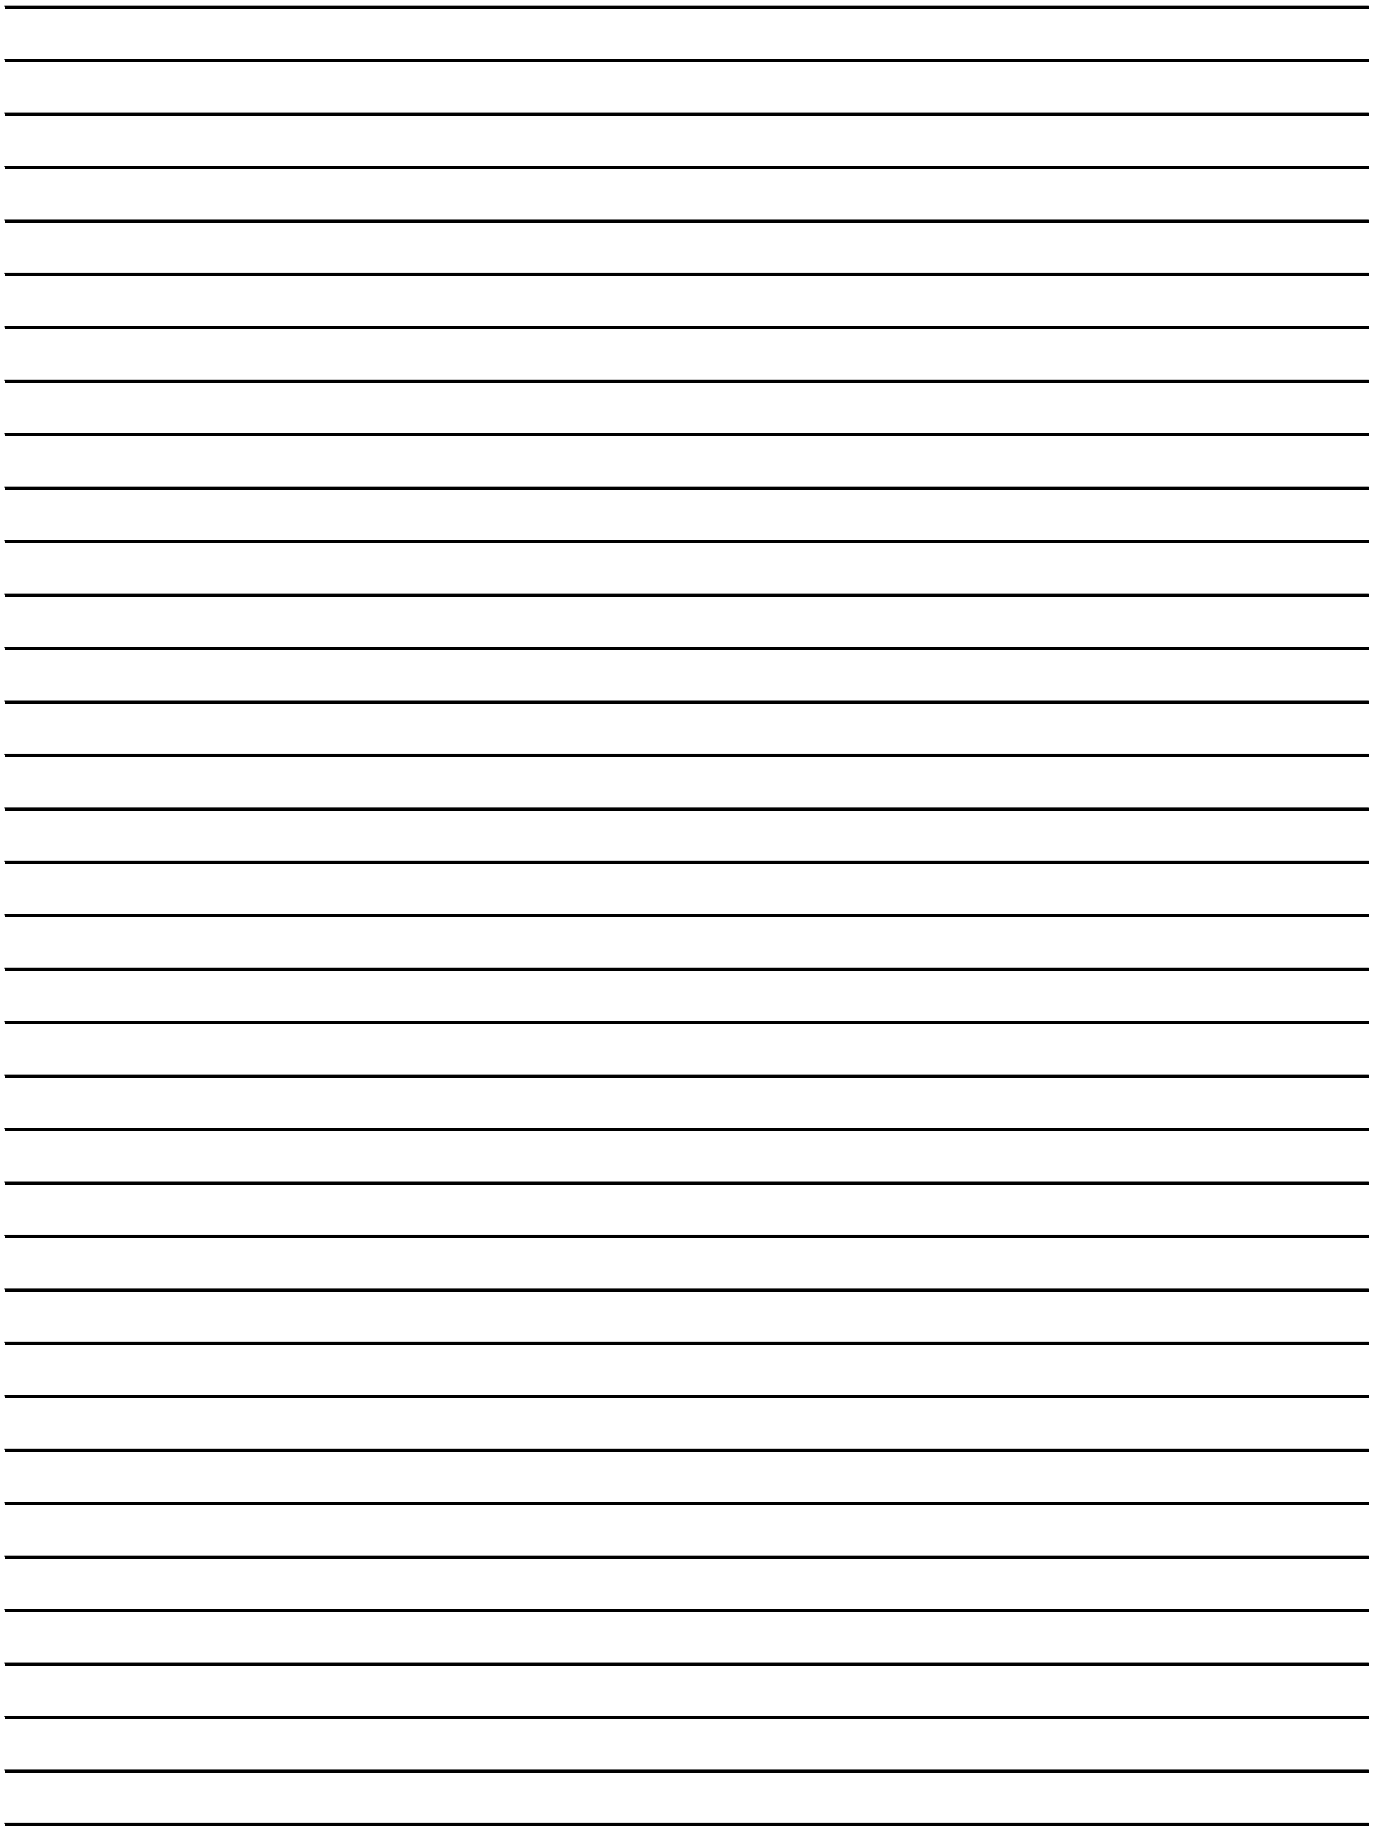

```
const addElements = () => {  
  // create a new div element  
  const newElement = document.createElement("h1");  
  
  // set the h1's id  
  newElement.setAttribute("id", "sleeping-giant");  
  
  // and give it some content  
  const newContent = document.createTextNode("Jell-O, Burled!");  
  
  // add the text node to the newly created div  
  newElement.appendChild(newContent);  
  
  // add the newly created element and its content into the DOM  
  document.body.appendChild(newElement);  
  
  // append a second element to the DOM after the first one  
  const lastElement = document.createElement("div");  
  lastElement.setAttribute("id", "lickable-frog");  
  document.body.appendChild(lastElement);  
};  
// run script when page is loaded  
window.onload = addElements;
```

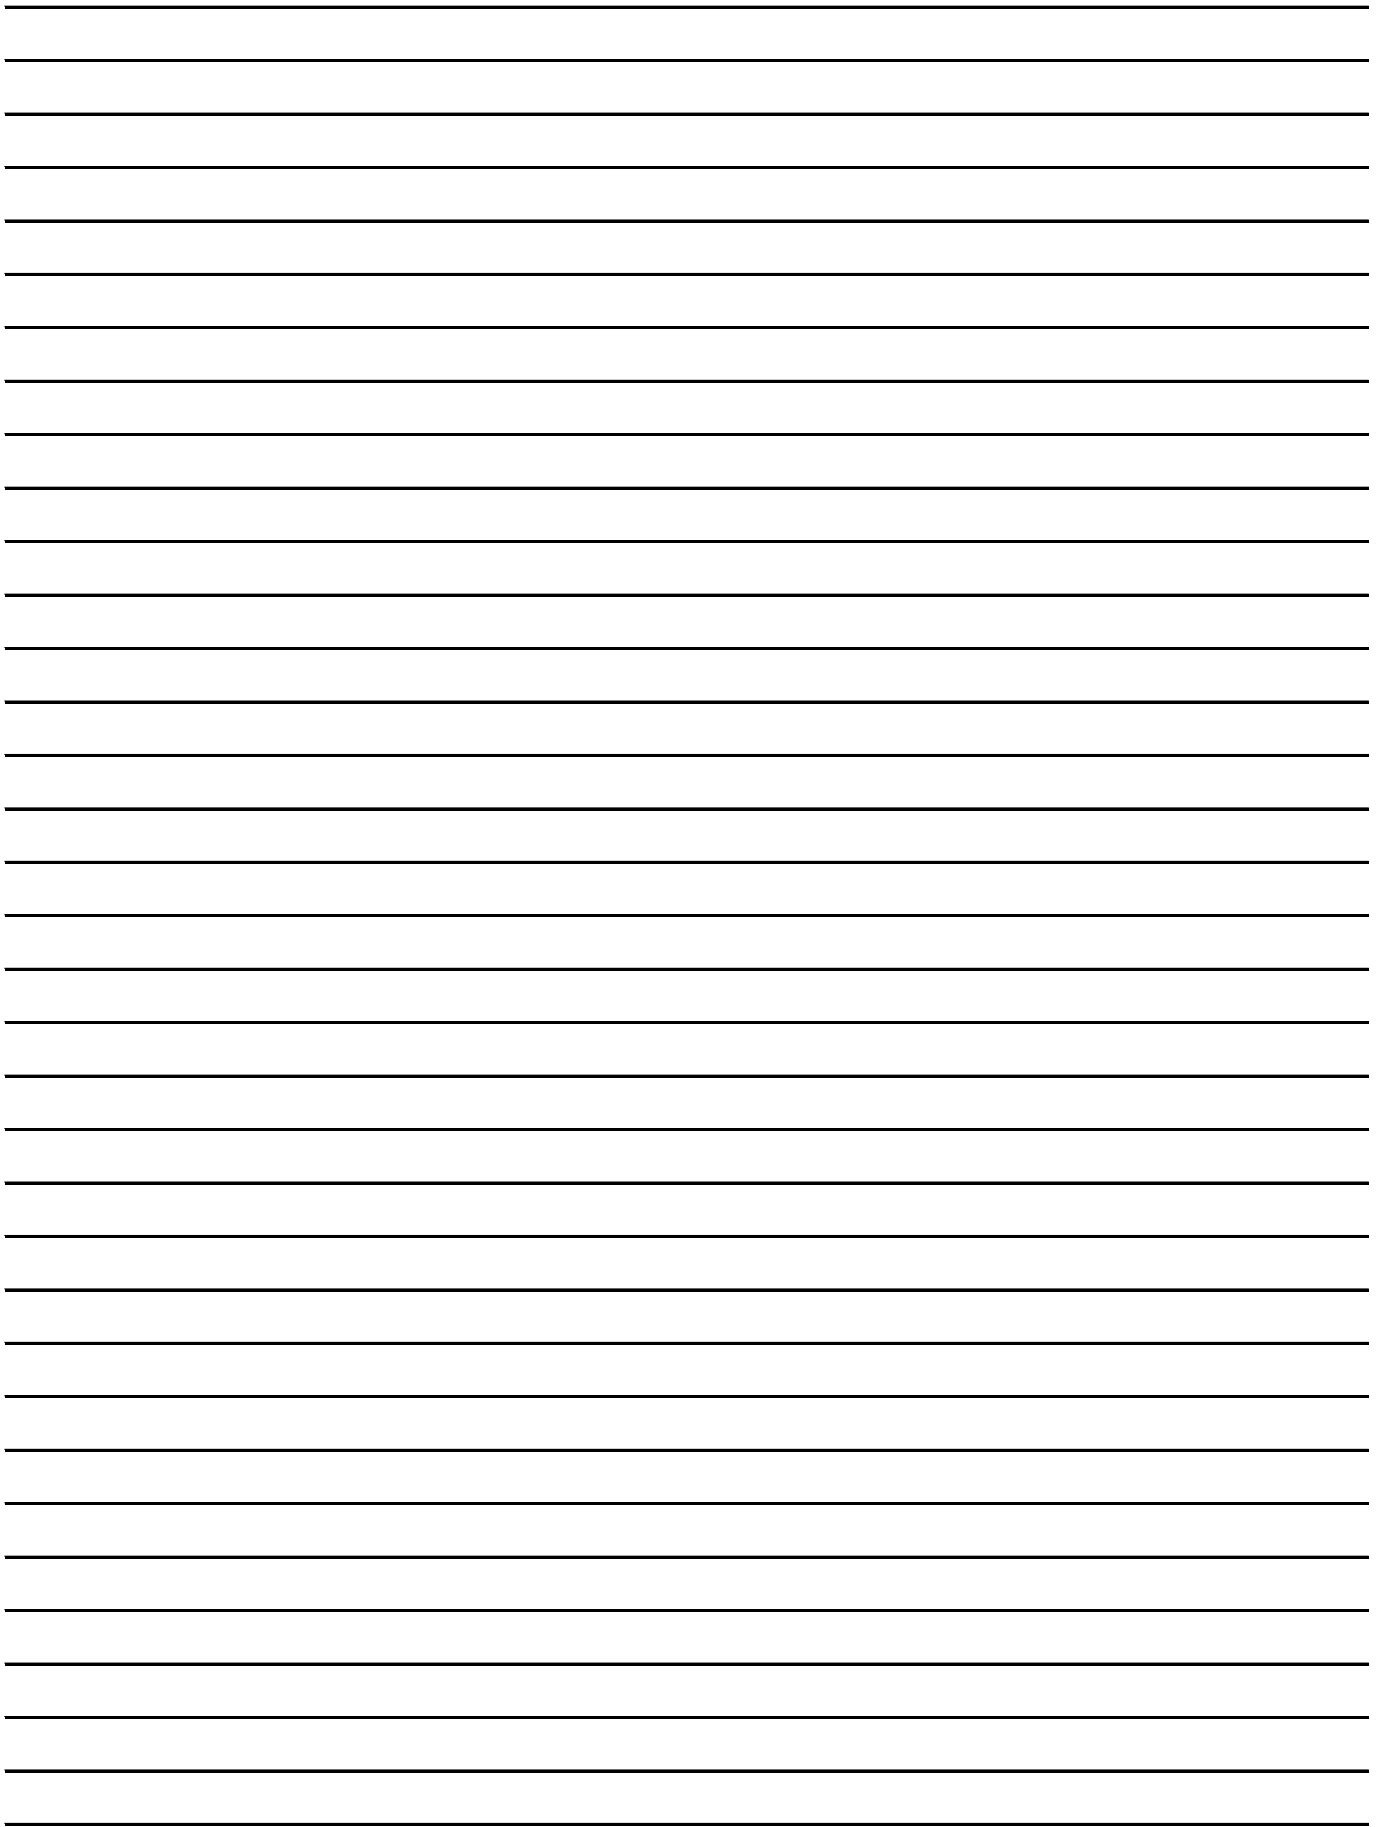

## HTML

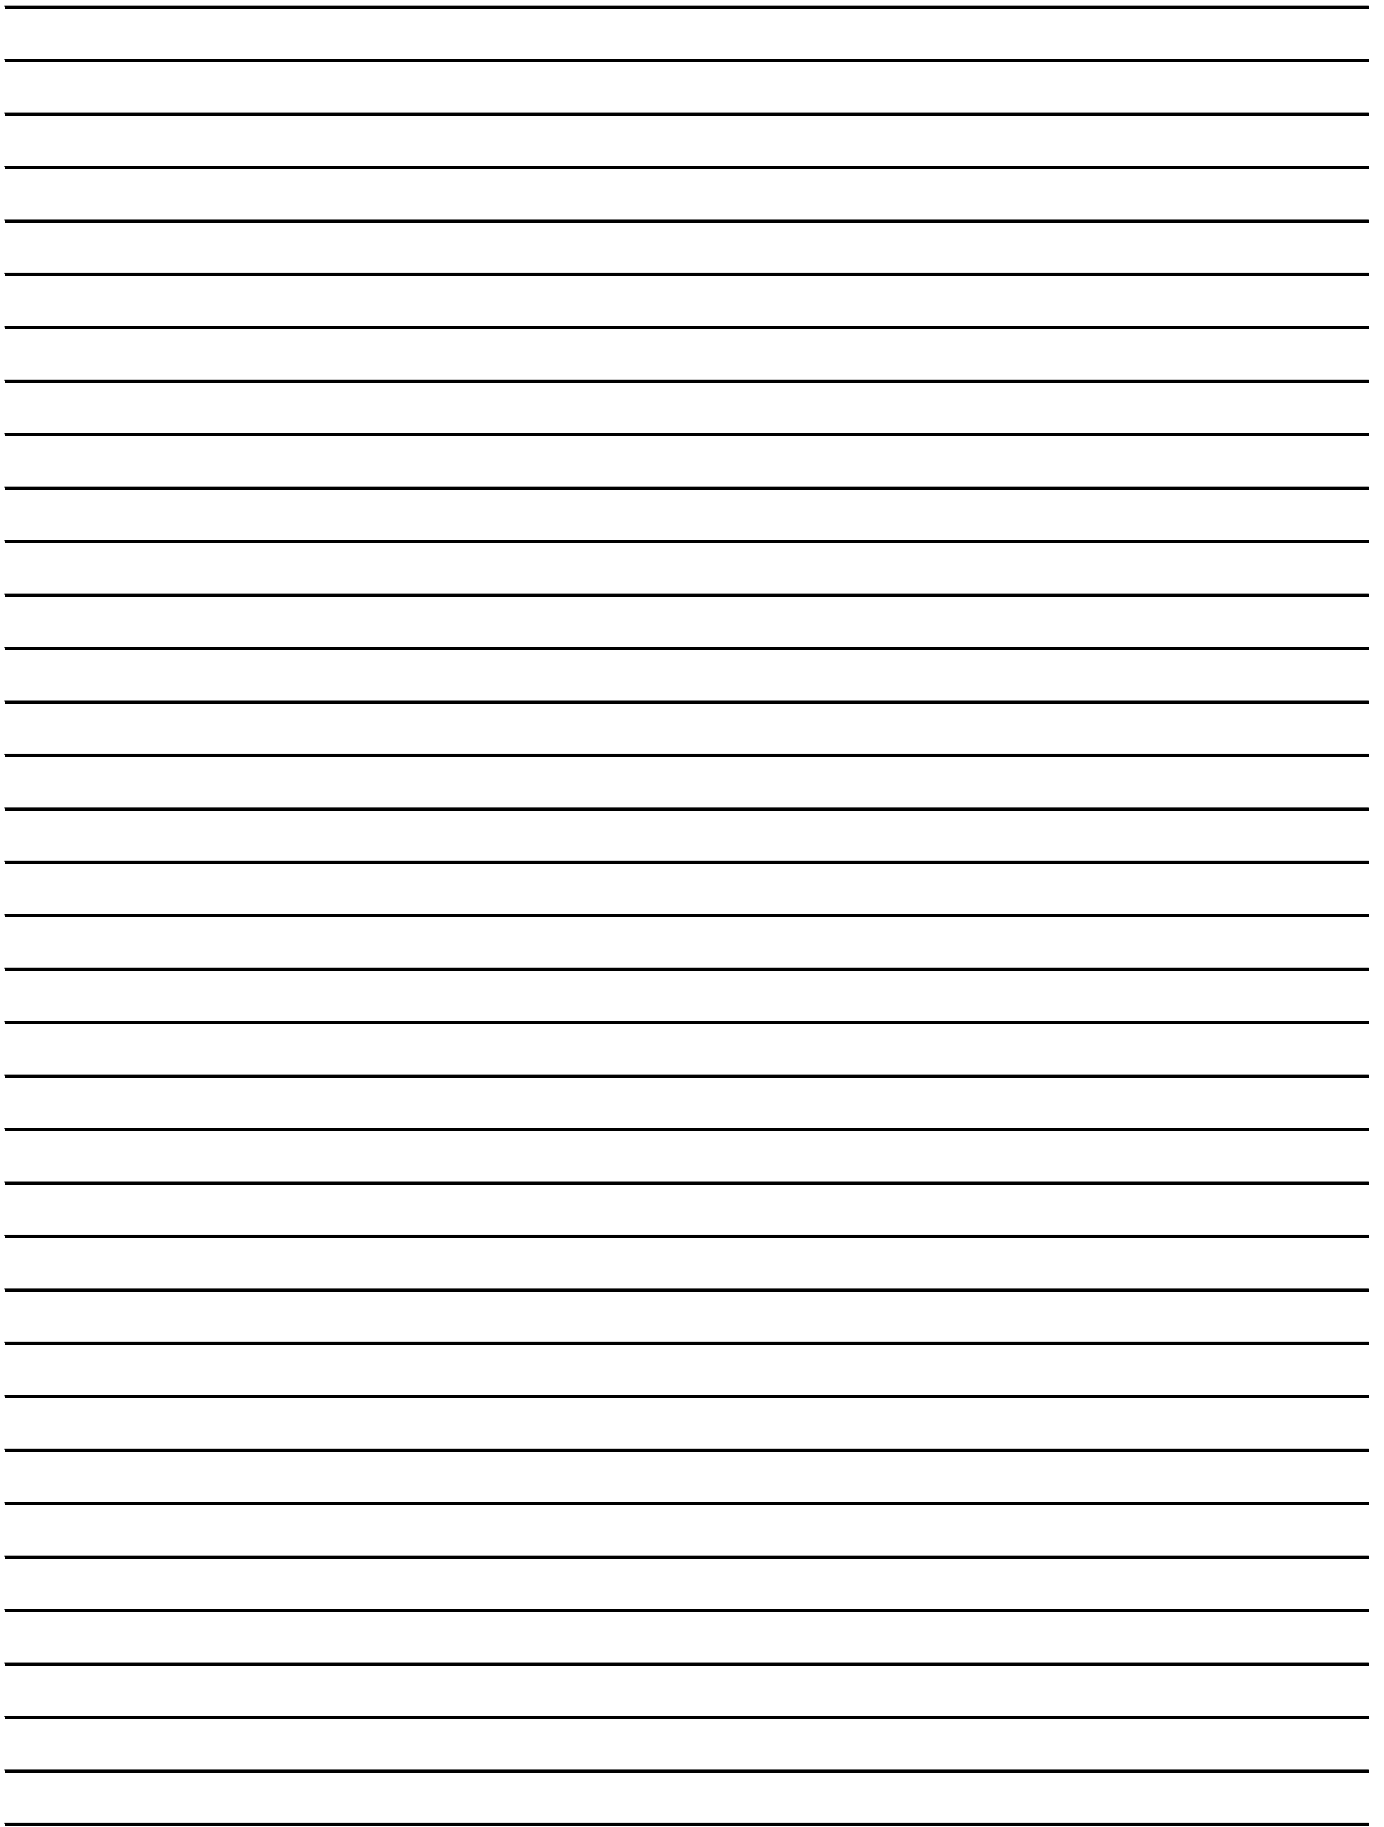

## JS

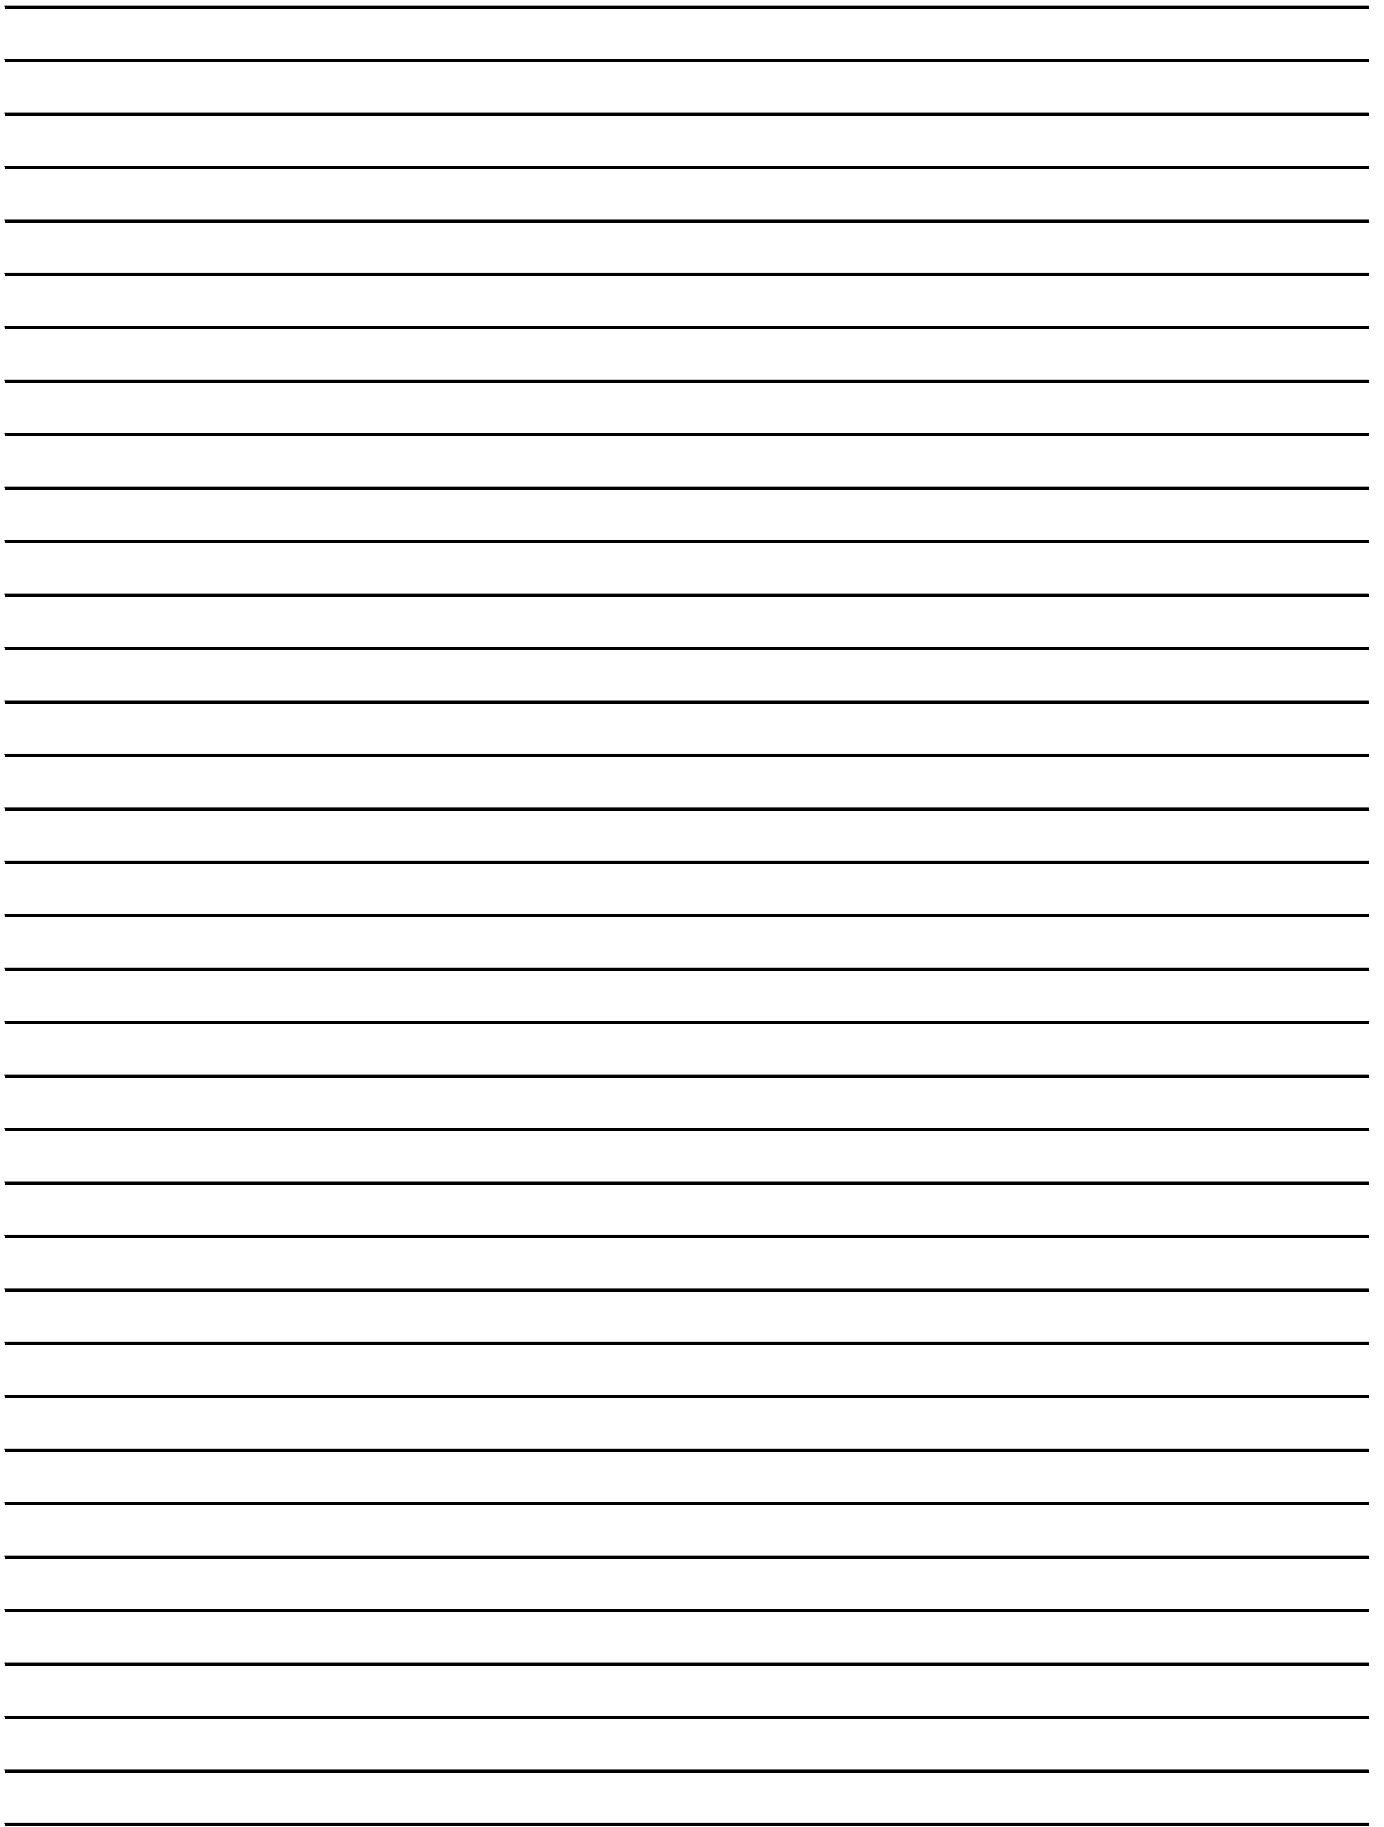

```
window.onload = () => {
  console.log(
    "This script loaded when all the resources and the DOM were ready."
  );
};
```

### Extra Info:

This method is implemented based on the ParentNode mixin's `querySelectorAll()` method.

### Usage notes

The capitalization of "Id" in the name of this method must be correct for the code to function; `getElementByID()` is not valid and will not work, however natural it may seem.

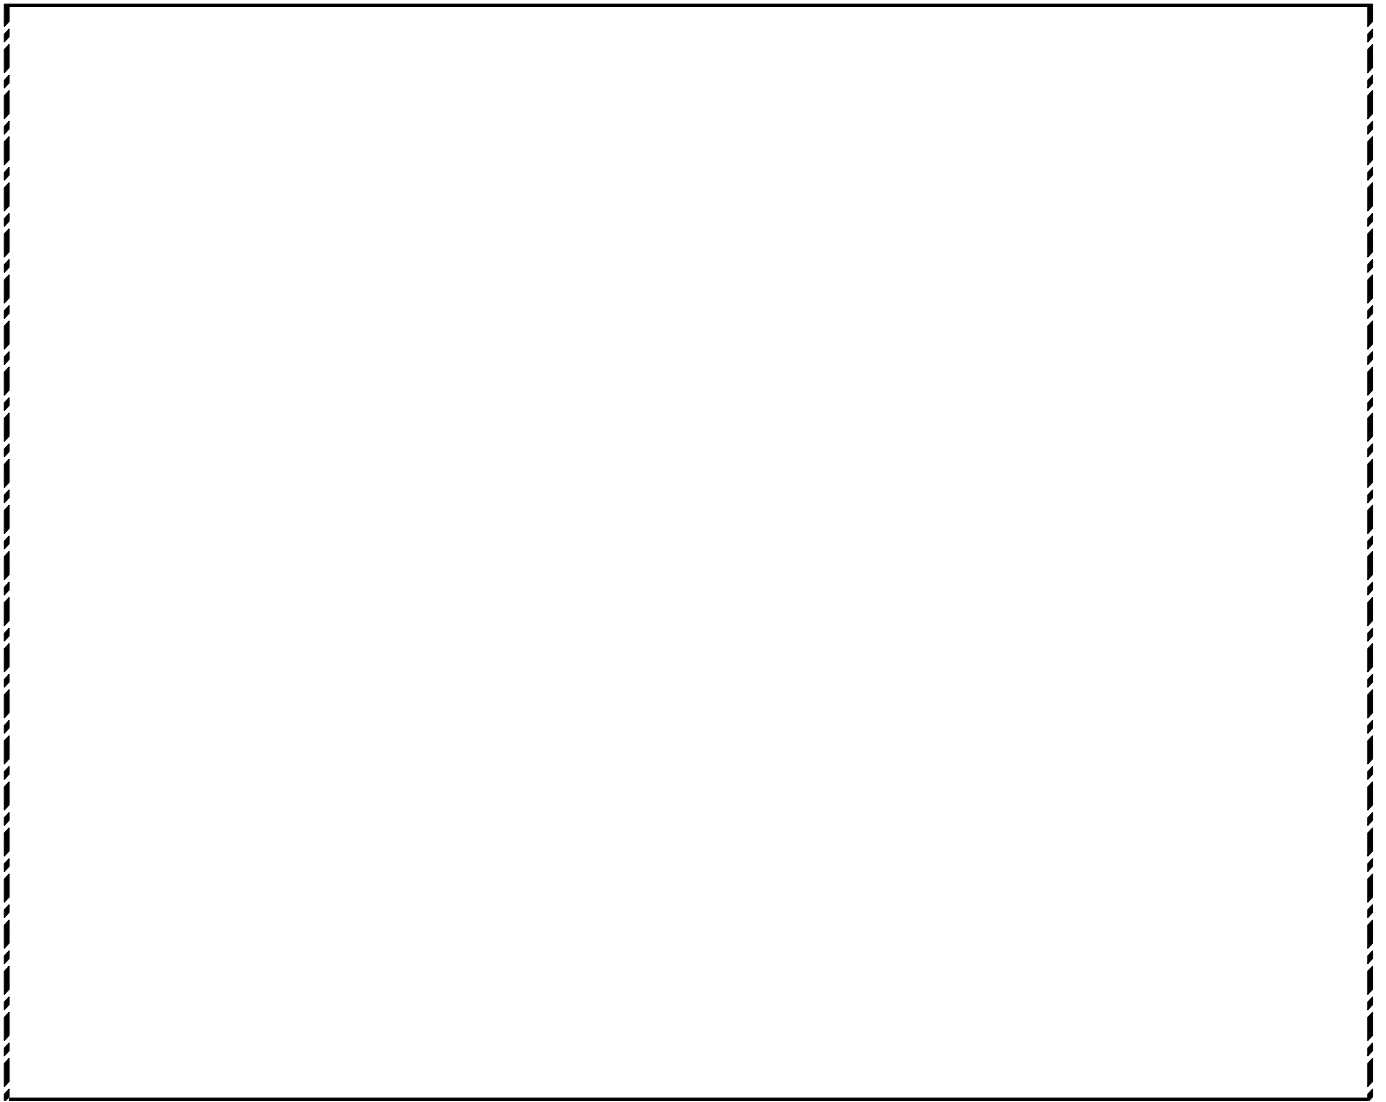

Unlike some other element-lookup methods such as `Document.querySelector()` and `Document.querySelectorAll()`, `getElementById()` is only available as a method of the global document object, and not available as a method on all element objects in the DOM. Because ID values must be unique throughout the entire d

Using `forEach()` on a `NodeList`:

### JavaScript

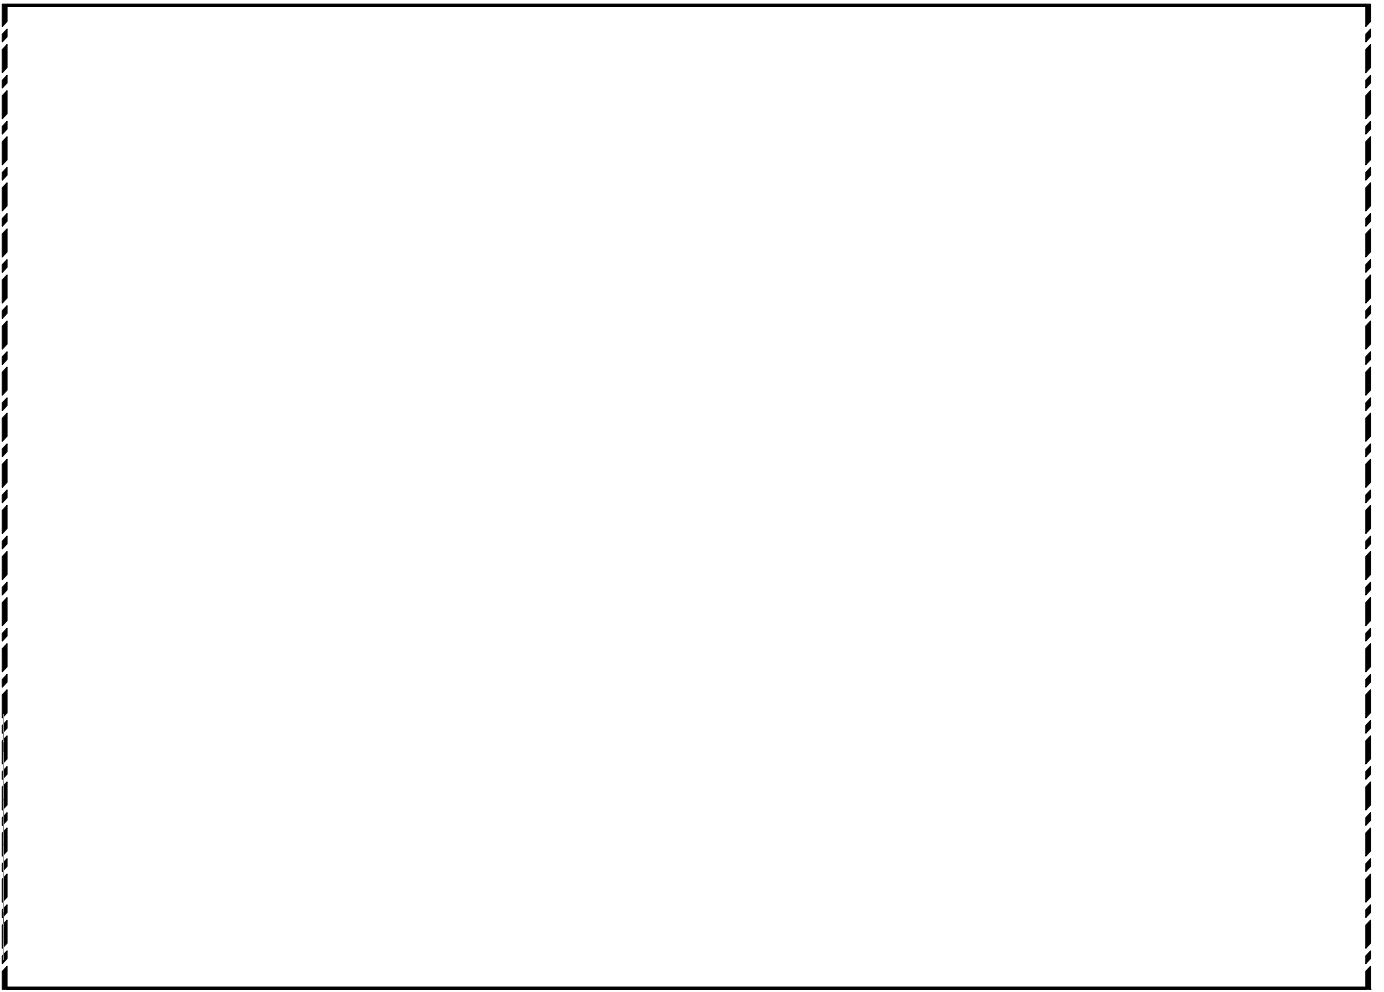

```
const cloudySpans = document.querySelectorAll("span.cloudy");

cloudySpans.forEach(span => {
  console.log("Cloudy!");
});
```

Boolean attributes are considered to be true if they're present on the element at all, regardless of their actual value; as a rule, you should specify the empty string ("") in value (some people use the attribute's name; this works but is non-standard). See the example below for a practical demonstration.

Since the specified value gets converted into a string, specifying null doesn't necessarily do what you expect. Instead of removing the attribute or setting its value to be null, it instead sets the attribute's value to the string "null". If you wish to remove an attribute, call `removeAttribute()`.

# Notes

Chaining may not work as expected, due to `appendChild()` returning the child element:

```
1 | let aBlock = document.createElement('block').appendChild( document.createElement('b') );
```

Sets `aBlock` to `<b></b>` only, which is probably not what you want.

`window.onload` fires when the document's window is ready for presentation and `document.onload` fires when the DOM tree (built from the markup code within the document) is completed.

Ideally, subscribing to DOM-tree events, allows offscreen-manipulations through Javascript, incurring almost no CPU load. Contrarily, `window.onload` can take a while to fire, when multiple external resources have yet to be requested, parsed and loaded.

This image shows a blank sheet of white paper designed for writing. It features horizontal blue or grey ruling lines spaced evenly down the page. A single dashed vertical line runs parallel to the left edge, creating a narrow margin. The paper is otherwise completely empty, with no text or markings.
