

# Git Reference:

## Local Repo

git init	Converts a local directory into a Git Repository
git status	See what is being tracked by Git within a Repository
git add . [file] [file] [file] *.txt	<ul style="list-style-type: none"><li>• Add everything within the directory to the repo</li><li>• Add specific files to the repo</li><li>• Add All txt files to the repo</li></ul>
git commit	A snapshot of all the files in the directory (repo)
git commit -m "<message>"	Write a message that describes the commit
git commit --amend	Alter the latest commit
git diff --staged <commit> <commit>^! <from commit> <to commit>	<ul style="list-style-type: none"><li>• See the changes within the working directory</li><li>• See the changes in the Staged Area</li><li>• See the changes within a specific commit</li><li>• See the changes between a specific commit and the commit before it</li><li>• See the changes between 2 specific commits</li></ul>
git branch ...	Creates a parallel commit
git checkout ...	Changes where HEAD is
git checkout -b ...	Creates a parallel commits and moves HEAD there
git merge ...	Merges parallel branches
git rebase ...	<ul style="list-style-type: none"><li>• Takes a set of commits, copies them, and puts them down somewhere else</li><li>• Keeps a cleaner commit log / history of the repository</li></ul>
git log	Used to see hashes
^	Move upwards one commit (per ^)

~<num>	Move upwards a number of times (don't use <> )
git branch -f master HEAD~3	<ul style="list-style-type: none"> <li>• Directly reassign a branch to a commit</li> <li>• (moves the master brand to three parents behind HEAD)</li> </ul>
git reset ...	<ul style="list-style-type: none"> <li>• Reverse changes by moving a branch reference backward to an older commit</li> <li>• Used for local git repos</li> </ul>
git revert ...	<ul style="list-style-type: none"> <li>• Reverse changes and <i>share</i> those reversed changes with others</li> <li>• Used for remote git repos</li> </ul>
git cherry-pick <commit> <commit> <commit>	Copy a series of commits below your HEAD
git cherry-pick <source>..<destination>	Copy a specific commit source to a specific branch destination
git rebase -i	<ul style="list-style-type: none"> <li>• Open up a UI to show which commits are about to be copied below the target</li> <li>• Shows their commit hashes and messages</li> <li>• Ability to do 3 things:</li> <li>• Reorder commits by changing their order in the UI</li> <li>• Choose to completely omit some commits <ul style="list-style-type: none"> <li>◦ toggling pick off means you want to drop the commit</li> </ul> </li> <li>• Squash commits... essentially allows you to combine commits <ul style="list-style-type: none"> <li>◦ (this aspect has been glossed over)</li> </ul> </li> </ul>
git tag v1 c1	<ul style="list-style-type: none"> <li>• Permanently mark "milestones" that can be referenced like a branch</li> <li>• CANNOT change what is in the tagged commit</li> <li>• Tags exist as anchors in the commit tree that designate certain spots</li> <li>• Tags commit 'c1' as the 'version 1' prototype</li> <li>• if the commit is left off the command... then the Tags is placed on the HEAD</li> </ul>
git describe <ref>	<ul style="list-style-type: none"> <li>• Where you are relative to the closest "anchor" (aka Tag)</li> <li>• Useful when you need to get your bearings after moving too much within a commit tree</li> <li>• &lt;ref&gt; can be any commit</li> <li>• If &lt;ref&gt; is left out of the command, the default is HEAD</li> <li>• Output command: <ul style="list-style-type: none"> <li>• &lt;tag&gt;_&lt;numCommits&gt;_g&lt;hash&gt;</li> <li>◦ &lt;tag&gt;: Closest anchor in history</li> <li>◦ &lt;numCommits&gt;: How many commits away that anchor is</li> <li>◦ &lt;hash&gt;: The commit being described</li> </ul> </li> </ul>

git checkout HEAD~^2~2	<ul style="list-style-type: none"> <li>• ^&lt;num&gt; will choose a different branch when trying to move upwards from a merged commit.</li> <li>• No number will move upwards directly above the merge.</li> <li>• ^&lt;num&gt; will move up the next closest branch</li> <li>• ~&lt;num&gt; moves up from the lowest commit within that branch</li> </ul>
------------------------	--

## REMOTE REPO

git clone	Create <i>local</i> copies of remote repositories
git fetch	<ul style="list-style-type: none"> <li>• Downloads the commits that the remote has but are missing from our local repository</li> <li>• updates where our remote branches point (for instance... o/master)</li> <li>• <b>Does Not:</b></li> <li>• Change anything about the local state</li> <li>• Update the master branch or change anything about how your file system looks right now</li> </ul>
git pull	<i>Fetching</i> remote changes and then <i>merging</i> them at once
git push	Uploading local changes to a specified remote, updating that remote to incorporate new commits
git pull --rebase Or git pull -r	<ul style="list-style-type: none"> <li>• <i>Fetch and Rebase</i></li> <li>• Pulls from remote and then rebases the current commit below</li> <li>• Changes we have made locally appear as if they were based on the latest version available from the remote repo</li> </ul>
git checkout -b totallyNotMaster o/master	Creates a new branch named totallyNotMaster and sets it to track origin/master
git branch -u o/master foo	<ul style="list-style-type: none"> <li>• Set remote tracking on a branch</li> <li>• Set the foo branch to track o/master</li> <li>• if foo is currently checked out, you can leave it off</li> <li>• git branch -u o/master</li> </ul>

git push <remote> <place>	<ul style="list-style-type: none"> <li>Tells git where the commits will <i>come from</i> and where the commits <i>will go</i></li> <li>By specifying both arguments, it <i>ignores where we are checked out</i></li> <li>&lt;place&gt; is essentially the "place" or "location" to synchronize between the two repositories</li> <li>Where it comes from</li> <li>&lt;remote&gt; is the remote repo name</li> </ul>
git push <remote> <source>:<destination>	<ul style="list-style-type: none"> <li>&lt;remote&gt; is the remote repo name</li> <li>&lt;source&gt; is the local commit we are pulling from</li> <li>&lt;destination&gt; is the remote commit we are pushing to</li> <li>If the destination doesn't exist, this command will create a new branch on the remote repo</li> </ul>
git fetch <remote> <place> <i>Can run 'pull' the same way</i>	<ul style="list-style-type: none"> <li>&lt;remote&gt; is the remote repo name</li> <li>&lt;place&gt; Grab all the commits from the remote branch and copies all commits that aren't present locally</li> </ul>
git fetch <remote> <source>:<destination> <i>Can run 'pull' the same way</i>	<ul style="list-style-type: none"> <li>&lt;remote&gt; is the remote repo name</li> <li>&lt;source&gt; is the local commit we are pulling from</li> <li>&lt;destination&gt; is the remote commit we are pushing to</li> <li>If the destination doesn't exist, this command will create a new branch on the local repo</li> <li><b>This command does NOT typically get used... because you MUST be sure</b></li> </ul>
git push <remote> :<destination>	<ul style="list-style-type: none"> <li>If there is no source, the &lt;destination&gt; gets deleted on the remote</li> </ul>
git fetch <remote> :<destination>	<ul style="list-style-type: none"> <li>Creates a new branch locally</li> </ul>
git stash	<ul style="list-style-type: none"> <li>A stack of changes on which you store any changes to the <i>Working Directory</i></li> <li>Place any modifications to the <i>Working Directory</i> on the stash</li> </ul>
git stash pop	<ul style="list-style-type: none"> <li>Take the latest change in the stash and apply it to the <i>Working Directory</i></li> <li>Remove the latest stashed change before applying it again</li> <li><b>I need further clarification on what's happening with this command</b></li> </ul>
git stash apply	<ul style="list-style-type: none"> <li>Do not remove latest changes before applying them</li> <li><b>Seek more clarification on what is happening with pop and apply modifiers</b></li> </ul>
git stash list	<ul style="list-style-type: none"> <li>Inspect the current stash and list individual entries</li> </ul>
git stash show	<ul style="list-style-type: none"> <li>Show the changes in the latest entry on the stash</li> </ul>

git stash branch <branch name>	<ul style="list-style-type: none"><li>• Create a branch, starting from the HEAD and apply the stashed changes to that branch</li></ul>
--------------------------------	--

### Initial Setup

- git config --global user.name "Your Name"
- git config --global user.email "email@example.com"

### Clone a repo off the remote server

- git clone git@example.com:user/repo local-repo-name

### Create a new repo locally

- git init
- git add .
- git status
- git commit -v -m "Initial commit."

### Connect your repo to a remote repo

- git remote add origin git@example.com:user/repo

### Normal Git workflow

1. Add and edit file(s)
2. Check the status of changes using `git status` or `git status -s` for a simpler version
3. Check exactly what you've changed within the files with `git diff` or `git diff --stat` for a simpler version
4. Add the changes you want to commit to the "staging area" with `git add`
5. Double-check your stages changes with `git status`
6. Commit the staged changes to your local repo with `git commit -m "message"`

### Change default strategy for *pull* to use *rebase* instead of *merge*

- git config --global pull.rebase true
